# **Towards Model Repair by** Human Opinion-Guided Reinforcement Learning

## Kyanna Dagenais

McMaster University – Hamilton, Canada dagenaik@mcmaster.ca | kyannadagenais.ca

## **Context and Research Problem**

## **Model repair**

#### Goal

▶ Repair invalid models by model transformations

#### Problem

 $\blacktriangleright$  Complex models  $\rightarrow$  long repair sequences Automation is needed

Model M	
	New M'

tion	actions (MT rules) mt1 mt2 mt3					
	s <sub>1</sub>	p <sub>11</sub>	<b>p</b> <sub>12</sub>	р <sub>13</sub>		
	tes s <sub>2</sub>	р <sub>21</sub>	<i>p</i> <sub>22</sub>	р <sub>23</sub>		
	sta s³	<b>р</b> 31	р <sub>32</sub>	р <sub>33</sub>		
$\neg$						

## **Reinforcement learning (RL)**

#### Basics

► Agent learns by trial and error

Pro: does not require historical data

► Policy: state to MT-rule mapping (probability)

#### Limitation

#### Opportunity

Modeling projects are longitudinally extensive Learn repair patterns as we go

Shallow learning curve (learning takes time)

#### Goal

Guide RL by rapidly emerging (uncertain) opinions

### Methods

Approach			Mapping betv	veen RL and MDE
Benchmark	Opinions	Subjective logic	RL	MDE
<ul> <li>Frozen Lake (Open AI)</li> <li>Performance metric:</li> </ul>	<ul> <li>Trade-off: early insights vs evidence</li> <li>By subjective logic</li> </ul>	<ul> <li>Probabilistic logic + uncertainty<sup>1</sup></li> <li>P=b+au</li> <li>A 100% uncertainty</li> </ul>	Frozen lake	Design space
cumulative reward		1=b+d+u	Agent	Current model state
		Uncertainty <i>discounts</i> the weight of belief	Action (step)	Model transformation
		75% 50% uncertainty	(0,0) Initial state	Invalid model
			Goal state	Valid model
$\sim \infty$	Human 📄 📑	0% 62.5% 100%	🛜 Terminal state	Model beyond repair
		<u>b</u> elief "75% sure, but I'm uncertain"	Evaluation	
Problem Space			<ul> <li>►12x12 version of the</li> <li>► Start→goal: ≥22</li> <li>► 20% of states me</li> <li>► Agent</li> </ul>	Frozen Lake steps arked terminal

Agent

Uniform probability distribution of actions

Opinions bias the agent's decisions

- Algorithm: discrete policy gradient
- ► Learning rate: 0.9
- ► Discount factor: 1.0
- ► Learning on 10 000 episodes
- ► Reward model
  - Terminal state: reward = 0
  - ► Goal state: reward = +1

## Results and takeaways

## Results

\*% denotes opinion quota, i.e., the number of opinions compared to the number of states

## Takeaways

## **Synthetic Oracle**

<u>Idealized</u> setup

-Access to the **whole** problem -Opinions about every state

-Uncertainty is **synthetic** 

## **Single Human Advisor**

<u>Idealized but humanlike</u> setup

- -Access to the **whole** problem
- -Opinions about **some** states
- -Uncertainty is **synthetic**

## **Two Cooperating Humans**

<u>Human</u> setup

-Access to **part of** the problem -Opinions about **some** states -Uncertainty is **measured**<sup>2,3</sup>

10000

10000

8000

8000

All opinions, even if uncertain, can be of **high utility**.

In the charts, cumulative reward tends to be significantly higher than "No advice" and "Random".

#### A single human advisor is **as** effective as a synthetic oracle.

Human Advisor" charts, "Single cumulative reward tends to be similar to that

of the "Synthetic Oracle" charts.

A single human advisor can be **more** efficient than a synthetic oracle.

In the "Single Human Advisor" charts, the same high reward is obtained at lower advice quotas (only 10% and 5% vs 100% and 20%).

Real cooperating humans' performance is **comparable** to that of synthetic advisors.

In the "Two Cooperating Humans" charts, cumulative reward tends to be similar to the other two cases.
